

QA Run Report: run_fcd9bc9c4f

■ Executive Quality Summary

Overall Quality Score: 60/100

Current Status: SUCCESS

■ Core Metrics Breakdown

Reliability Score: 80/100 (Static & Runtime Stability)

Validation Score: 40/100 (Business Logic Coverage)

Hallucination Risk: 0/100 (Ungrounded Logic Detectors)

Resilience Health: 40/100 (Error Handling & Retries)

■ Critical Security & Logic Findings

[HIGH] Missing required field: edges: The uploaded automation.json is missing the top-level edges field.

[HIGH] Workflow edges are missing: A node/edge workflow was uploaded without edges.

[MEDIUM] Workflow node type is not in the approved registry: Node collector declares unsupported type file_collector.

[MEDIUM] Workflow node type is not in the approved registry: Node planner declares unsupported type llm_planner.

[MEDIUM] Workflow node type is not in the approved registry: Node router declares unsupported type tool_router.

[MEDIUM] Workflow node type is not in the approved registry: Node executor declares unsupported type python_runner.

[MEDIUM] Workflow node type is not in the approved registry: Node memory declares unsupported type vector_memory.

[MEDIUM] Workflow node type is not in the approved registry: Node repair declares unsupported type self_healer.

[MEDIUM] Workflow node type is not in the approved registry: Node approval declares unsupported type approval_gate.

[MEDIUM] Workflow node type is not in the approved registry: Node notifier declares unsupported type email_sender.

[MEDIUM] Workflow node type is not in the approved registry: Node finalizer declares unsupported type finalizer.

[HIGH] Missing validation layer: The workflow has no explicit validation node or rule after execution steps.

[MEDIUM] Retry policy is missing: The workflow does not declare retry attempts, delays, or backoff strategy.

■ Autonomous Failure Explainer

Root Cause Analysis

The provided Python code snippet does not directly relate to the findings, which seem to be about workflow configuration and validation. However, the root cause of failure is likely due to the absence of essential configuration elements in the workflow definition, such as 'edges' and validation layers.

User Impact: If this goes to production, users may experience unpredictable behavior, errors, and potential data inconsistencies due to the lack of proper workflow configuration, validation, and error handling.

Recommended Fix: Define a complete and valid workflow configuration, including 'edges', approved node types, explicit validation layers, and a retry policy to ensure robustness and reliability.

■■ Autonomous Repair Strategies

Strategy: Database URL Fallback

Safety Score: 99.0%

Rationale: Using os.getenv for DB_URL provides a safe fallback

Suggested Code Patch:

```
import os
DATABASE_URL = os.getenv("DB_URL", "sqlite:///memory:")
API_SECRET = os.getenv("API_SECRET", "default_api_secret")
# rest of the code...
```

Strategy: API Secret Fallback

Safety Score: 99.0%

Rationale: Using os.getenv for API_SECRET provides a safe fallback

Suggested Code Patch:

```
import os
DATABASE_URL = os.getenv("DB_URL", "sqlite:///memory:")
API_SECRET = os.getenv("API_SECRET", "default_api_secret")
# rest of the code...
```

Strategy: Enhanced Error Handling

Safety Score: 95.0%

Rationale: Using try/except blocks for import crashes provides a safe way to handle errors

Suggested Code Patch:

```
import os
try:
    DATABASE_URL = os.getenv("DB_URL")
    if not DATABASE_URL:
        DATABASE_URL = "sqlite:///memory:"
    API_SECRET = os.getenv("API_SECRET")
    if not API_SECRET:
        API_SECRET = "default_api_secret"
except Exception as e:
    print(f"Error occurred: {e}")
    DATABASE_URL = "sqlite:///memory:"
    API_SECRET = "default_api_secret"
# rest of the code...
```

■ Agent Execution Timeline

05:41:42 **reflection**: Agent reflection active (running)

05:41:42 **reflection**: Transitioned to reflection (running)

05:41:44 **failure_explainer**: The provided Python code snippet does not directly relate to the findings, which seem to be about workflow configuration and validation. However, the root cause of failure is likely due to the absence of essential configuration elements in the workflow definition, such as 'edges' and validation layers. (success)

05:41:44 **memory_retriever**: Agent memory_retriever active (running)

05:41:44 **memory_retriever**: Transitioned to memory_retriever (running)

05:41:45 **memory_retriever**: Retrieved 3 past fixes. (success)

05:41:45 **self_heal_router**: Agent self_heal_router active (running)

05:41:45 **self_heal_router**: Transitioned to self_heal_router (running)

05:41:48 **self_heal_router**: Proposed 3 fixes (success)

05:41:48 **memory_writer**: Agent memory_writer active (running)

05:41:48 **memory_writer**: Transitioned to memory_writer (running)

05:41:52 **retry_or_replan**: Agent retry_or_replan active (running)

05:41:53 **retry_or_replan**: Transitioned to retry_or_replan (running)

05:41:53 **finalizer**: Agent finalizer active (running)

05:41:53 **finalizer**: Transitioned to finalizer (running)
